

Clinical Trial Data

The clinical trials of Ulcelocin Oral Ulcer Patch were conducted using a double-blinded method on 90 patients with recurrent oral mucosa ulcers at the multi-centered national key dental schools authorized by the Chinese SFDA according to the current good clinical practice procedures.

Healing condition(size of the remaining ulcer wound in diameter during the treatment, mm)

Pain index(eating)

The above are the comparison data of the patients treated with Ulceloocin Oral Ulcer Patch (study group) and the patients without any treatment (control group). The effectiveness of treatment was measured by healing condition and pain index. Pain index indicates the degree of pain due to the ulcer during eating. Healing condition indicates the size of remaining ulcer surface before and during the treatments.

The results demonstrated that Ulceloocin Oral Ulcer Patch significantly relived pain($P<0.01$) and effectively promoted healing of the ulcer surfaces($P<0.01$).
